#### **ABSTRACT**

We propose a generalized version of the L2HMC algorithm (Lévy et al., 2018), and evaluate its ability to sample from different topologies in a two-dimensional lattice gauge theory. In particular, we demonstrate that our model is able to successfully mix between modes of different topology, significantly reducing the computational cost required to generate independent gauge configurations.

#### 1 Introduction

## **TODO:** Complete introduction

## 2 BACKGROUND

#### 2.1 HAMILTONIAN MONTE CARLO

The Hamiltonian Monte Carlo (HMC) algorithm is a widely used technique that allows us to sample from an analytically known target distribution p(x) by constructing a chain of states  $\{x^{(0)}, x^{(1)}, \dots, x^{(n)}\}$ , such that  $x^{(n)} \sim p(x)$  in the limit  $n \to \infty$ . For our purposes, we assume that our target distribution can be expressed as a Boltzmann distribution,  $p(x) = \frac{1}{Z}e^{-S(x)} \propto e^{-S(x)}$ , where S(x) is the *action* of our theory. In this case, HMC begins by augmenting the state space with a fictitious momentum variable v, normally distributed independently of x, i.e.  $v \sim \mathcal{N}(0, 1)$ . Our joint distribution can then be written as

$$p(x,v) = p(x) \cdot p(v) \propto e^{-S(x)} \cdot e^{-\frac{1}{2}v^T v} = e^{-\mathcal{H}(x,v)}$$
 (1)

where  $\mathcal{H}(x,v)$  is the Hamiltonian of the joint (x,v) system. Notably, this system obeys Hamilton's equations

$$\dot{x} = \frac{\partial \mathcal{H}}{\partial v}, \quad \dot{v} = -\frac{\partial \mathcal{H}}{\partial x}$$
 (2)

which can be integrated using the *leapfrog integrator* along iso-probability contours defined by  $\mathcal{H} = \text{const.}$  Explicitly, for a step size  $\varepsilon$  and initial state  $\xi = (x, v)$ , the leapfrog integrator generates a proposal configuration  $\xi' \equiv (x', v')$  by performing the following series of updates:

1. Half-step momentum update:  $v^{1/2} \equiv v \left(t + \frac{\varepsilon}{2}\right) = v - \frac{\varepsilon}{2} \partial_x S(x)$ 

2. Full-step position update:  $x'\equiv x(t+\varepsilon)=x+\varepsilon v^{1/2}$ 

3. Half-step momentum update:  $v' \equiv v(t+\varepsilon) = v^{1/2} - \tfrac{\varepsilon}{2} \partial_x S(x')$ 

We can then construct a complete *trajectory* of length  $\lambda = \varepsilon \cdot N_{\rm LF}$  by performing  $N_{\rm LF}$  leapfrog steps in sequence. At the end of our trajectory, we either accept or reject the proposal configuration according to the Metropolis-Hastings acceptance criteria,

$$x_{i+1} = \begin{cases} x' & \text{with probability } A(\xi'|\xi) \\ x & \text{with probability } (1 - A(\xi'|\xi)). \end{cases}$$
 (3)

where

$$A(\xi'|\xi) = \min\left\{1, \frac{p(\xi')}{p(\xi)} \left| \frac{\partial \xi'}{\partial \xi^T} \right| \right\}. \tag{4}$$

The generic leapfrog integrator is known to be symplectic (conserves energy), so the Jacobian factor reduces to  $\left|\frac{\partial \xi'}{\partial \xi^T}\right| = 1$ .

## 2.2 GENERALIZING THE LEAPFROG INTEGRATOR: L2HMC

In (Lévy et al., 2018), the authors propose the L2HMC ("Learning to Hamiltonian Monte Carlo") algorithm, and demonstrate its ability to outperform traditional Hamiltonian Monte Carlo (HMC) on a variety of two-dimensional target distributions. For example, the trained L2HMC sampler is shown to be capable of exploring regions of phase space which are typically inaccessible with traditional HMC. Additionally, they show that the trained sampler is efficient at mixing between modes of a multi-modal target distribution, a feature which is highly desirable for MCMC simulations of lattice gauge theory.

**Notable changes:** Compared to the original implementation, we carry throughought the updates a discrete index k parameterizing the current leapfrog step, for  $k = 0, 1, \ldots, N_{\rm LF}$ . In doing so, we are free to consider the case where we use different update functions (Equation 5, Equation 6) for different leapfrog steps.

We denote a complete state by  $\xi=(x,v,d)$  with target distribution  $p(\xi)=p(x,v,d)=p(x)\cdot p(v)\cdot p(d)$ . Here we've introduced a (uniformly drawn) binary direction variable  $d\in\{-,+\}$  that determines the "direction" of our update, and is distributed independently of both x and v. The key modification of the L2HMC algorithm is the introduction of six auxiliary functions  $s_i,t_i,q_i$  for i=x,v into the leapfrog updates, which are parameterized by weights  $\theta$  in a neural network.

For simplicity, we consider the forward d = +1 direction, and introduce the notation:

$$v'_{k} \equiv \Gamma_{k}^{+}(v_{k}; \zeta_{v_{k}})$$

$$= v_{k} \odot \exp\left(\frac{\varepsilon}{2} s_{v}^{k}(\zeta_{v_{k}})\right) - \frac{\varepsilon}{2} \left[\partial_{x} S(x_{k}) \odot \exp\left(\varepsilon q_{v}^{k}(\zeta_{v_{k}})\right) + t_{v}^{k}(\zeta_{v_{k}})\right],$$

$$x'_{k} \equiv \Lambda^{\pm}(x_{k}; \zeta_{x_{k}})$$

$$= x_{k} \odot \exp(\varepsilon s_{x}^{k}(\zeta_{x_{k}})) + \varepsilon \left[v'_{k} \odot \exp(\varepsilon q_{x}^{k}(\zeta_{x_{k}})) + t_{x}^{k}(\zeta_{x_{k}})\right]$$
(6)

where (1.)  $\zeta_{v_k}=(x_k,\partial_x S(x_k),\tau(k))$ , and  $\zeta_{x_k}=(x_k,v_k,\tau(k))$  are subsets of the augmented space independent of the variable being updated (v,x) respectively), (2.)  $\tau(k)=\left[\cos\frac{2\pi k}{N_{\rm LF}},\sin\frac{2\pi k}{N_{\rm LF}}\right]$ ,  $k=0,1,\ldots,N_{\rm LF}$ , is a discrete time variable parameterizing our trajectory, and (3.) we indicate the forward d=+1 direction by the + superscript on  $\Gamma^+$ ,  $\Lambda^+$  respectively.

This allows us to write the complete leapfrog update (in the forward d = +1 direction) as:

- 1. Half-step momentum update:  $v_k' = \Gamma_k^+(v_k; \zeta_{v_k})$
- 2. Full-step half-position update<sup>1</sup>:  $x'_k = \overline{m}^t \odot x_k + m^t \odot \Lambda_k^+(x_k; \zeta_{x_k})$
- 3. Full-step half-position update:  $x_k'' = \overline{m}^t \odot \Lambda_k^+(x_k'; \zeta_{x_k'}) + m^t \odot x_k'$
- 4. Half-step momentum update:  $v_k'' = \Gamma^+(v_k'; \zeta_{v_k'})$

Note that in order to keep our leapfrog update reversible, we've split the x update into two subupdates by introducing a binary mask  $m^t = m^t \odot \mathbb{1} + \bar{m}^t \odot \mathbb{1}$  that updates half of the components of x sequentially, as shown in Figure 1. As in HMC, we form a complete trajectory by performing  $N_{\rm LF}$  leapfrog steps in sequence, followed by a Metropolis-Hastings accept/reject step as described in Equation 4. However, unlike in the expression for HMC, we must take into account the Jacobians of each of the transformations which are easily computed to give

$$\left| \frac{\partial v_k'}{\partial v_k} \right| = \exp\left(\frac{\varepsilon}{2} s_v^k(\zeta_{v_k})\right), \quad \left| \frac{\partial x_k'}{\partial x_k} \right| = \exp\left(\varepsilon s_x^k(\zeta_{x_k})\right). \tag{7}$$

In order to perform the updates in the generalized leapfrog integrator, we need to evaluate the functions s,t,q in the respective updates. We maintain separate networks with identical architectures for updating the x and y components separately. For simplicity, we temporarily ignore the discrete

<sup>&</sup>lt;sup>1</sup>By this we mean we are performing a complete update step that only updates half of the components of x determined by the mask  $m^t$  and its complement  $\bar{m}^t$ .

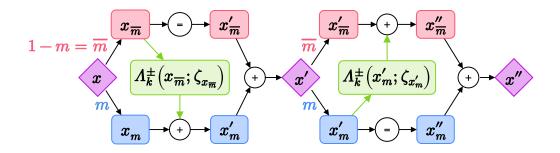

Figure 1: Illustration of the split x update.

leapfrog index k, and restrict our attention to the  $s_x, t_x, q_x$  functions used in the x update equation,  $x_k = \Lambda^+(x; \zeta_x)$  and note that the v update (Equation 5) is identical.

Each of the  $s_x, t_x, q_x$  functions takes as input  $\zeta_x = (x, v, \tau)$ , with  $x \in \mathbb{R}^n$ ,  $v \in \mathbb{R}^n$ , and  $\tau \in \mathbb{R}^2$ . The network splits these inputs and constructs the following intermediate variable

$$z_1 = \sigma(w_x^T x + w_y^T v + w_\tau^T \tau + b).$$
(8)

This intermediate variable  $z_1$  is then passed through another series of fully-connected layers,

$$z_n = \sigma(w_n^T z_{n-1} + b_n), \ z_{n-1} = \sigma(w_{n-2}^T z_{n-2} + b_{n-2}), \ \dots, \ z_2 = \sigma(w_2^T z_1 + b_2).$$
 (9)

The network outputs  $s_x, t_x, q_x$  are then defined in terms of this final hidden variable  $z_n$  as

$$s_x(\zeta_x) = \alpha_s \tanh(w_s z_n + b_s), \quad t_x(\zeta_x) = w_t^T z_n + b_t, \quad q_x(\zeta_x) = \alpha_q \tanh(w_q z_n + b_q) \quad (10)$$

where  $\alpha_s$ , and  $\alpha_q$  are trainable scaling factors. The only requirement on the details of the network is that the dimensionality of the outputs  $s_x, t_x, q_x$  match the dimensionality of our physical variables  $x, v \in \mathbb{R}^n$ .

Next, we introduce a loss function

$$\mathcal{L}_{\theta}(\xi, \xi', A(\xi'|\xi)) = -\frac{\delta(\xi, \xi')}{a^2} \tag{11}$$

where  $\delta(\xi, \xi')$  is a suitably chosen *metric function*, and a is a scaling factor.
